

Finite passages and holonomy in Clebsch matching geometry

Tavis Rudd

Exploratory split draft — July 2026

Abstract

Several finite constructions attached to the Clebsch matching geometry retain different parts of the same orientation data. We organize their survival and loss through carrier torsors and a four-sheet cover with explicit cycle holonomy. The resulting comparison links finite passages with theta, Fourier, quantum, Mathieu, and characteristic-zero realizations. The first purpose of this draft is to determine whether these comparisons form one theorem complex with a standalone mathematical question.

Keywords. Clebsch configuration; finite cover; holonomy; torsor; Fourier transform; Mathieu group.

2020 Mathematics Subject Classification. 05B25, 20B25, 20C20, 81P45.

1 Introduction

The candidate paper asks when orientation data survives passage between the finite models attached to the Clebsch matching geometry. Before the prose is expanded, C579 must identify one principal theorem and show that the remaining comparisons are consequences rather than coequal narratives.

Standalone-value gate. This skeleton inventories a possible theorem order. It adopts no claim until C575 pins its source and C579 shows that the carrier and holonomy constructions answer one question without depending on the narrative of the rigidity or factorization papers.

2 Carriers, orientations, and passage maps

Define the common carrier data and the torsors transported by each passage. State the determinant-sign transport mechanism before introducing the individual realizations.

3 Survival and loss

Turn the passage-survival tables into mathematical propositions: identify what is retained, what is erased, and which negative statements are strict. Keep table entries subordinate to these propositions.

4 The four-sheet cover and cycle holonomy

Define the six-column pencil, its covectors, the linear sheaf, and the four-sheet cover before stating the holonomy theorem. Derive the resonances and relative-frame counts from cycles, and keep the strict survival boundary separate from parent reconstruction.

5 Theta, Fourier, and quantum realizations

State the exact comparison functors and their hypotheses. Separate finite monomial or fixed-party statements from any broader equivalence that is not proved.

6 Mathieu and characteristic-zero bridges

Explain which torsor is common to the finite Mathieu construction and the characteristic-zero realization. Make every identification and normalizer computation visible at its actual proof mode.

7 Verification architecture

Map the carrier, holonomy, survival, and comparison statements to their conceptual proofs, Lean interfaces, and finite certificates. Record the exceptional-prime boundary without turning the section into a workflow transcript.

Conclusion

If the standalone-value gate passes, conclude with the exact invariant transported across all adopted passages and the first passage at which it is lost. Otherwise this material returns to a results inventory rather than a paper.
